

Theories, Methods & Strategies for Sustainable Landscape Planning

Citation: 2005. Ahern, Jack. Theories, methods and strategies for sustainable landscape planning, Tress, B., Tress, G., Fry, G., Opdam, P. (eds.) 2005. From landscape research to landscape planning: Aspects of integration, education and application. Springer.

Abstract

Sustainability is an international policy goal with multiple dimensions and implications for planning. Landscape planning prescribes alternative spatial configurations of land uses, which is widely understood as a key factor in planning for sustainability. Theories of landscape planning and sustainability are briefly reviewed, and a typology to organize and classify is presented. Selected methods for sustainable landscape planning are reviewed according to the typology. Challenges, barriers and strategies to the implementation of sustainable landscape planning are discussed with recommendations and methods referenced.

Keywords

Sustainability, landscape planning, spatial configuration

Introduction

This chapter discusses theory, methods and challenges to sustainable landscape planning. Three principle sectors of planning have been recognized historically; physical/spatial, policy, social and economic. Sustainable planning is an activity intent on integrating these three sectors across social, economic and environmental arenas. Sustainable planning aspires to link knowledge about sustainability with actions to achieve it. Sustainable planning thus “implements” or “operationalizes” the principles of sustainability in planning theory and practice.

Landscape ecological planning is a specialization within landscape planning that focuses on spatial planning, the organization of uses and relationships of land uses to achieve explicit goals (e.g. habitat improvement, sustainability). While, the landscape ecological planning approach is characterized by a focus on the linkage of ecological patterns and processes, it also includes the actions and values of humans, and social and economic dimensions (Hersperger 1994). Finally, landscape ecological planning adopts the landscape as the principle spatial unit of research and planning recommendations. The focus of this chapter is on landscape ecological planning and on planning for sustainability.

A Typology for Classifying Sustainable Landscape Planning Methods

For operational planning practice, it is useful to organize the number of approaches, frameworks and methods currently available for sustainable landscape planning under a typology based. I offer the following typology as a basis for this organization. The typology includes 5 subcategories: 1) theoretical orientation: substantive or procedural; 2)

resource or goal orientations; 3) interdisciplinary : transdisciplinary; 4) strategic orientation and 5) spatial concepts.

1. Theoretical Orientation

Ndubisi argues there are two fundamental types of theory in landscape planning: substantive and procedural (1997). Substantive theories are descriptive and prescriptive and originate from basic research in the natural and social sciences and the humanities. Substantive theories support a better understanding of the landscape as an interface of natural and cultural processes and articulate the ideology, purpose, and principles of sustainable landscape planning. The value of the information derived from substantive theories is a function of how the information is organized, presented and understood by planners. Island biogeography and metapopulation theory are examples of substantive theories that are increasingly applied in landscape ecological planning. These theories are particularly relevant when planning is focused on biodiversity conservation or restoration. The application of these theories has led to criticism by ecologists who argue, for example, that conservation corridors are not a panacea to solve the biodiversity crisis, and that corridors may, in fact, cause unintended negative effects on biodiversity (Simberloff and Cox 1987). Other examples of substantive theories that have influenced landscape planning include, prospect:refuge and habitat theory; central place theory and transactive and participative theory.

Procedural theories offer recommendations for putting substantive theory into practice. They focus on methodological issues, such as suitability analysis, optimal land use allocation, and applied landscape ecological planning. Planners draw on substantive theories for information and guidelines but use procedural theories as a framework to organize information in a form that readily permits the more direct application of information in addressing landscape planning problems (Ndubisi, 1997). An informed planner, therefore, will be aware of the substantive theories that guide and inform the operational methods that are applied in planning.

2. Resource or Goal Orientation

Planning methods can also be understood and classified according to their resource or goal orientation. The abiotic-biotic-cultural (ABC) model is useful describe the specific goals addressed in planning and the level of integration between these goals (Ahern 1995, Leitao et al in preparation). In this model, abiotic goals include water resources, soil, and air quality. Biotic goals focus on biodiversity in general, including individual species and habitat protection and ecological restoration. Cultural goals are human-based and include: transportation, land use, recreation, historic preservation, and economic goals. Figure 1 presents an array of planning types graphically organized within a triangle that represents the ABC model. In this diagram a number of planning sectors or themes are located according to their emphasis and level of integration within the ABC resources. The figure shows that an evolution is occurring towards a more integrated planning perspective as represented by the center circle.

3. Interdisciplinarity and Transdisciplinarity

The trend towards interdisciplinarity and transdisciplinarity is central to sustainable planning and provides another useful tool to understand and classify planning methods. As discussed above, planning is arguably evolving towards an integrated, or balanced approach wherein multiple abiotic, biotic and cultural goals are simultaneously pursued. Historically, this integration has involved knowledge and participation from multiple disciplines, initially under a multidisciplinary approach in which disciplines operated with minimal interaction and collaboration. Under the interdisciplinary approach, researchers and professionals from multiple disciplines collaborated, shared information and achieved a higher level of synthesis and integration. Contemporary researchers argue that transdisciplinarity represents a yet higher level of integration in which professionals, non-academic and academic participants participate in a process in which knowledge is shared across disciplines and all participants are engaged in decision making (Tress et al 2004). Under the transdisciplinary model, planning may become more integrated with research, enabling the multidimensional challenge of sustainability to be understood more rigorously with many disciplines involved, and the public (i.e. stakeholders, elected officials) are similarly involved in planning and decision making. The level of transdisciplinarity has become a key indicator of rigorous sustainability planning.

4. Strategic Orientation

Planning methods can also be classified and understood according to their strategic orientation: protective, defensive, offensive or opportunistic (Ahern 1995). These strategies, in essence, define the planning context with respect to the macro drivers of change in a given landscape and the strategic nature of the planners' response. Defining these strategies also helps to place the planning activity within a broader context that is particularly important when planning methods are transferred or adopted for use in different locations, contexts or for different applications.

When the existing landscape supports sustainable processes and patterns, a protective strategy may be employed. Essentially, this strategy defines an eventual, or optimal landscape pattern that is proactively protected from change while the landscape around it may be allowed to change. **Benton MacKaye's (1928) vision of a metropolitan open space system structured by a system of protected "dams" and "levees" is a classic example from north America.** It can be effective to prevent landscape fragmentation in urbanizing landscapes by pre-defining a patch and corridor network for protection, for example. This strategy employs planning knowledge, regulation, and land acquisition to

achieve the desired spatial configuration (goal).

When the existing landscape is already fragmented, and core areas already limited in area and isolated, a defensive strategy is often applied. This strategy seeks to arrest /control the negative processes of fragmentation or urbanization. As a last resort, the defensive strategy is often necessary, but it can also be seen as a reactionary strategy which attempts to “catch up with” or “put on the brakes”, against the inevitable process of landscape change, in defense of an ever-decreasing nature (Sijmons 1990).

An offensive strategy is based on a vision, or a possible landscape configuration that is articulated, understood and accepted as a goal. The offensive strategy differs from protective and defensive strategies in that it employs restoration, or reconstruction, to rebuild landscape elements in previously disturbed or fragmented landscapes. The offensive strategy relies on planning knowledge, knowledge of ecological restoration, and significant public support/ funding. It requires, by definition the displacement, or replacement of intensive land uses (e.g. urbanization, agriculture) with extensive land uses. This strategy is often practiced in locations where intensive land use has produced a cultural landscape with limited opportunities for nature protection or defense. The offensive strategy essentially involves “putting nature back” into the landscape, according to an accepted vision or plan. It is rarely practiced because it is expensive and often politically sensitive.

A landscape often contains unique elements or configurations that represent special opportunities for sustainable landscape planning. These unique elements may or may not be optimally located, but represent the potential to provide particular desired functions. The rails-to-trails movement in the USA is a good example of opportunistic greenway planning (Little 1990, Flink and Searns 1993). This strategy is dependent on the presence of certain unique landscape elements, such as abandoned rail corridors. The opportunistic strategy involves recognition of special opportunities to add other functions to these corridors and to effect future landscape configuration to support ecological, or cultural processes.

A planner should be aware of the drivers of change in a given landscape with respect to the goals of a particular plan. This awareness is the basis for informing a planner’s choice of methods, and of engaging the appropriate participants in the planning process.

5. Spatial Concepts

Spatial concepts guide, inspire and communicate the essence of a plan or planning strategy. Spatial concepts are often articulated as metaphors, that are highly imageable and understandable by the public, but which also can support and inspire the planning process (Zonneveld 1991). Examples include: “green heart”, “ring city”, and “edge city”. Spatial concepts are well understood in planning, but less understood in science. They represent an important interface of empirical and intuitive knowledge through which rational knowledge is complemented with creative insights. Spatial concepts are

essential tools for proactive, or innovative planning, and can structure and inspire the planning process, particularly with respect to public participation – a key factor in transdisciplinary planning.

Figure 2 presents a series of basic spatial concepts for planning. These can be understood as a kind of “strategic tool box” with which planners can articulate strategies that respond to the given landscape context and configuration and the forces and dynamics of landscape change with the intention of planning a more sustainable spatial pattern.

Insert Figure 2 here

Figure 2. Basic Spatial Concepts for Landscape Planning

An example of a more comprehensive spatial concept is Forman’s “Aggregate with Outliers Principle” which addresses the provocative question “What is the optimum arrangement of land uses in a landscape?” (Forman 1995, p. 437). Forman’s concept states that land uses should be aggregated; yet maintain small corridors and small patches of nature throughout developed areas, as well as outliers of human activity spatially arranged along major boundaries. This strategic model for spatial planning which addresses multiple landscape ecological goals: maintains large patches of native vegetation; accommodates human needs/preferences; contains a variance of grain size, supports generalist and specialist species, spreads risks, supports genetic variation, and accommodates outliers located along a boundary zone.

Another important spatial concept in sustainable planning is the “Framework Concept” which is based principally on abiotic geo-hydrological landscape patterns which can be isolated and managed to provide for a linked network or framework of “low dynamic” functions (i.e. nature development”). Within the “gaps” of the framework, are complementary opportunities for “high dynamic” land uses (e.g. “intensive agriculture, or urbanization” (van Buuren and Kerkstra 1993).

Figure 3. The Framework Concept, (van Buuren and Kerkstra, 1993)

The typology presented above is intended to frame a more informed and transparent discussion and distinction among the many approaches and methods available for planning. As planning methods embrace the challenge of sustainability, integration and adaptation of existing methods will become necessary to address varying needs and goals. When a planner understands more explicitly how the methods can be distinguished, as by applying this typology, a more informed choice of method(s) may be made. Following are three procedural planning methods that may be relevant, or adaptable, to implement sustainable landscape planning across a range of contexts.

Selected Sustainable Landscape Planning Methods

Three planning methods will be briefly presented and discussed in terms of the typology presented. All three are considered procedural methods, intended to operationalize the planning process.

Ecological Planning Model

Steiner's Ecological Planning Model (EPM) (1991,2000) addresses multiple abiotic, biotic and cultural goals, with a focus on land use allocation. The EPM is an 11-step procedure for studying the biophysical and socio-cultural systems of a place/landscape to reveal where specific land uses may best be practiced. It is based on Ian McHarg's Ecological Planning Method. The EPM includes an emphasis on goal establishment, implementation, administration and public participation through systematic education and citizen involvement throughout the process. It can be considered transdisciplinary as it involves professionals, experts and citizens in a highly interactive process. The framework is adaptable to multiple strategic contexts and it employs spatial concepts in the form of design explorations at a finer scale. The EPM has been applied effectively across a range of cultural and environmental contexts.

Figure 4: The Ecological Planning Model (Steiner 2000)

Framework Method for Landscape Planning

Steinitz' Framework Method for Landscape Planning (1990,1995) is presented as a series of 6 questions that are fundamental to landscape planning:

1. Representation: How should the state of the landscape be described in terms of content, boundaries, space, and time?
2. Process: How does the landscape work? What are the functional and structural relationships among its elements?
3. Evaluation: How does one judge whether the current state of the landscape is working well? The metrics of judgment include: beauty, habitat diversity, cost, nutrient flow, public health, or user satisfaction.
4. Change/Intervention: By what actions might the current representation of the landscape be altered (whether conserving or changing the landscape)?
5. Impact: What predictable differences might the changes cause? (I.e. using process models to simulate change)
6. Decision: How is the decision to change (or conserve) the landscape to be made? How is a comparative evaluation to be made among the alternative courses of action?

Steinitz' framework provides a robust and flexible process for assessing a landscape, and for engaging scientific experts, professionals, and stakeholders in an informed, iterative and participatory planning process. The framework is suited to address multiple ABC goals, and is adaptable to any strategic planning context. It can be considered transdisciplinary as it integrates public and expert participation. The framework does not include spatial concepts per se, however in practice it develops alternative future scenarios that represent a form of spatial concept.

Insert Figure 5. here

Figure 5. Framework Method for Landscape Planning (Steinitz 1995)

Framework Method for Sustainable Landscape Ecological Planning

The Framework Method for Sustainable Landscape Ecological Planning explicitly addresses multiple ABC goals and resources (Ahern 1995, 1999). The Framework is presented as a linear process, but actually is nonlinear, cyclical and iterative and may be entered at any point in the process (e.g. planning could start with a reevaluation of an existing plan). It was conceived to be transdisciplinary, as it includes knowledge from science, planning and stakeholders and citizens. The method explicitly acknowledges the strategic context, and relies on spatial concepts to resolve patterns of spatial compatibility and conflict. This method is based largely on landscape ecological theory and concepts, as understood and applied through spatial assessments and spatial concepts. As with Steinitz' method, this framework guides the planning process through a series of alternative future scenarios, to inform, inspire and challenge the decision making process to link planning actions with potential outcomes. The scenarios describe a current situation, some alternative future(s) and the necessary steps or actions needed to link the present with the future. These scenarios are not intended to be complete plans, but are appropriate for encouraging informed discussion of alternatives. The scenarios are evaluated, with public, expert and stakeholder input. The discussion leads to a landscape plan, which is adaptive in terms of implementation, monitoring and education.

Barriers, Challenges, and Strategies to Implement Sustainable Landscape Planning

The preceding typology and discussion of selected methods was presented to frame the subject of sustainable landscape planning. It is not intended as a comprehensive analysis or review of the subject. Regardless of the method selected, or adapted, significant barriers and challenges exist to the implementation of sustainable landscape plans. Chief among these are: uncertainty and adaptability.

Uncertainty is inherent in multipurpose planning. Uncertainty exists in several principal forms relative to planning: geographical/spatial, temporal, process, transferability, and human input unpredictability. Strategies from science are helpful to aid planners in reducing uncertainty, including: replication and pseudoreplication of data, the use of data analogues, developing multiple hypotheses, and monitoring.

Planners operate in the 'real world' where there is an imperative to act. The world doesn't stop, or wait while planners work to collect data to reduce uncertainty. Planning operates on a target that is, by definition, moving. The adaptive approach re-conceives uncertainty as an opportunity to "learn by doing". Adaptive management has been

practiced in resource management for at least two decades, but has not yet been widely integrated into planning. Adaptive management re-conceives management actions as experiments that have testable hypotheses (Rutledge and Lepczyk, 2002). Whereas traditional management hesitated to apply new policy decisions until proof of efficacy was obtained through long and short term empirical studies, adaptive management is a proactive method, under which projects and policy decisions are used as ‘experimental probes,’ to learn by doing (Holling, 1978, Walters 1986). Data made available upon the outcome of each policy decision or model implemented is used to structure alternative and future choices (Walters and Holling, 1990), attempting to reduce the amount of uncertainty and improving ecological knowledge and understanding over time. Monitoring is the primary tool used to gauge the efficacy of decisions made, and is itself the subject to wide range of uncertainty. In the adaptive approach, uncertainty lies in determining appropriate systems or populations of study, spatial-temporal scales, and geographic extent. Under a traditional planning/decision making approach, decisions on each of these areas of uncertainty would be made before a plan was implemented and before a monitoring program could be designed. Under an adaptive approach, these principle areas of uncertainty (determining appropriate systems or populations of study, spatial-temporal scales, and geographic extent) can become part of adaptive hypotheses, which can then inform both planning and monitoring actions and interpretations.

To achieve a true adaptive planning method will require a process that is genuinely transdisciplinary. Adaptive planning requires that the planner accept a certain level of uncertainty and risk, maintain a commitment to monitoring, and perhaps most importantly to be willing to fail.

Thresholds and guidelines represent important alternatives to adaptive planning, and can aid sustainable planning. Dale et al (2000) developed the following generic guidelines for land use planning and management that serve an important function in framing the key issues and questions, and to inform sustainable planning decisions:

1. Examine the impacts of local decisions in a regional context
2. Plan for long-term change and unexpected events
3. Preserve rare landscape elements and associated species
4. Avoid land uses that deplete natural resources over a broad area.
5. Retain large contiguous or connected areas that contain critical habitats.
6. Minimize the introduction and spread of non-native species
7. Avoid or compensate for effects of development on ecological processes
8. Implement land use and land management practices that are compatible with the natural potential of the area.

The Environmental Law Institute developed a series of conservation thresholds intended to inform biodiversity planning (2003). The thresholds are based on a systematic literature review to synthesize quantitative scientific findings and to present specific recommendations regarding key conservation planning parameters including: minimum patch area by species type, proportions of suitable habitat, size of edge effects and riparian buffer width. While this level of generalization may be unacceptable to

scientists, under an adaptive planning model, they could be applied and tested, thus potentially yielding new knowledge.

Conclusions

The global focus on sustainability is influencing planning theory to converge in several respects. There is a distinct focus on spatial planning at a broad/landscape scale in recognition of the widespread acceptance of substantive theories from landscape ecology. Under the sustainability paradigm, single purpose, sectoral planning is being replaced with multipurpose planning that explicitly acknowledges the integrated continuum of abiotic, biotic and cultural resources goals. The complexity and scale of broad scale, multipurpose planning necessitates a transdisciplinary approach to address the complexity of the challenge, while engaging citizens affected by the plan in meaningful ways. If there is a frontier in sustainable planning, I believe it lies in the development of an adaptive approach to planning in which plans are made with the best knowledge available, but with explicit acknowledgement of uncertainty, followed by monitoring and re-evaluation of plans in order to close the loop, and to “learn by doing”.
