Beyond Schiff: Atomic EDMs from two-photon exchange

Satoru Inoue
(work with Wick Haxton & Michael Ramsey-Musolf)
ACFI Workshop, November 6, 2014
Outline

• Very short review of Schiff theorem

• Multipole expansion as an expansion in powers of $R_N/R_A$

• 2-photon exchange appears to give larger atomic EDM than Schiff moment by 2 orders of magnitude - first, naive derivation

• Full derivation - the answer is essentially the same

• Relativistic enhancement is larger for Schiff moment (in progress)
Schiiff theorem

Derivation relies on 3 assumptions:

1. Constituent particles are point-like

2. Non-relativistic dynamics

3. Only electrostatic interactions
Derivation relies on 3 assumptions: Loopholes

1. Constituent particles are point-like
   - Nuclear size - Schiff moment

2. Non-relativistic dynamics
   - Relativistic electrons - paramagnetic systems

3. Only electrostatic interactions
   - Electromagnetic currents - topic of this talk
Natural size of interactions

Schiff theorem is the cancellation between these diagrams

Schiff theorem is the cancellation between these diagrams

\[ C_1 \]

indicating that the photon couples to the nuclear EDM

Electron-nucleus interaction here is

\[
V_{C_1} = - \frac{4\pi \alpha}{3} \int d^3 x \frac{\rho_e(\vec{x})}{x^2} Y_1(\hat{x}) \otimes \int d^3 y y \rho_N(\vec{y}) Y_1(\hat{y})
\]

\[
= - \frac{4\pi \alpha}{3} \frac{R_N}{R_A^2} C_1^A \otimes C_1^N
\]

lengths can be divided out
Natural size of interactions

This comes from multipole expansion of Coulomb potential

$$V_{\text{Coul}} = -\alpha \int \int d^3x d^3y \frac{\rho_e(\vec{x})\rho_N(\vec{y})}{|\vec{x} - \vec{y}|}$$

Electron is usually outside the nucleus \((x > y)\)

$$\frac{1}{|\vec{x} - \vec{y}|} = \sum_{lm} \frac{4\pi}{2l+1} \left( \frac{y^l}{x^{l+1}} \theta(x - y) + \frac{x^l}{y^{l+1}} \theta(y - x) \right) Y_{lm}^*(\hat{x}) Y_{lm}(\hat{y})$$

$$= \sum_{lm} \frac{4\pi}{2l+1} \left[ \begin{array}{c} y^l \\ x^{l+1} \end{array} \right] + \left( \frac{x^l}{y^{l+1}} - \frac{y^l}{x^{l+1}} \right) \theta(y - x) \right] Y_{lm}^*(\hat{x}) Y_{lm}(\hat{y})$$

Green terms survive in limit of point-like nucleus

l-th multipole interaction goes as $$\sim \frac{4\pi\alpha}{R_A} \left( \frac{R_N}{R_A} \right)^l$$
Natural size of interactions

This comes from multipole expansion of Coulomb potential

\[ V_{\text{Coul}} = -\alpha \int \int d^3x d^3y \frac{\rho_e(\vec{x}) \rho_N(\vec{y})}{|\vec{x} - \vec{y}|} \]

Electron is usually outside the nucleus \((x > y)\)

\[
\frac{1}{|\vec{x} - \vec{y}|} = \sum_{lm} \frac{4\pi}{2l + 1} \left( \frac{y^l}{x^{l+1}} \theta(x - y) + \frac{x^l}{y^{l+1}} \theta(y - x) \right) Y_{lm}^*(\hat{x}) Y_{lm}(\hat{y})
\]

\[
= \sum_{lm} \frac{4\pi}{2l + 1} \left[ \frac{y^l}{x^{l+1}} + \left( \frac{x^l}{y^{l+1}} - \frac{y^l}{x^{l+1}} \right) \theta(y - x) \right] Y_{lm}^*(\hat{x}) Y_{lm}(\hat{y})
\]

Penetration terms are the effects of nonzero nuclear size

They are suppressed by nuclear vs atomic volume \(\left( \frac{R_N}{R_A} \right)^3\)
Natural size of interactions

Schiff moment contribution comes from penetration terms

Schiff moment electron-nucleus potential looks like

\[
V_{\text{Sch}} = \left( \frac{4\pi \alpha}{R_A} \right) \left( \frac{R_N}{R_A} \right)^3 \left[ R_A^4 \sum_i \left( \frac{\vec{\nabla}_i \delta^3(\vec{x}_i)}{3} + \delta^3(\vec{x}_i) \vec{\nabla}_i \right) \right] \odot \vec{S}
\]

\( \vec{S} \) - nuclear Schiff moment operator with lengths divided out

Volume factor - \( \left( \frac{R_N}{R_A} \right)^2 \) times smaller than EDM potential
Breit interaction

1-γ exchange at LO in non-relativistic expansion

\[ V_{\text{Breit}} = -\alpha \int \int d^3x d^3y \left[ \frac{\rho_e \rho_N}{|\vec{x} - \vec{y}|} - \frac{1}{2} \left( \frac{\vec{j}_e \cdot \vec{j}_N + (\vec{j}_e \cdot \hat{n})(\vec{j}_N \cdot \hat{n})}{|\vec{x} - \vec{y}|} \right) \right] \]

Current-current interaction have their own multipoles

Transverse magnetic - magnetic dipole, quadrupole, etc.

\[ M_{lm}^N = \int d^3y \left( \frac{y}{R_N} \right)^l \left[ Y_l(\hat{y}) \otimes \vec{j}_N(\vec{y}) \right]_{lm} \quad \text{note the powers of } y \]

Transverse electric -

\[ E_{lm}^N = i \sqrt{(l + 1)(2l + 1)} \int d^3y \left( \frac{y}{R_N} \right)^{l-1} \left[ Y_{l-1}(\hat{y}) \otimes \vec{j}_N(\vec{y}) \right]_{lm} \]
Dividing out length scales as we did for charge multipoles, we find the following natural sizes for multipole interactions:

\[
\begin{array}{l|l}
V_{Cl}, V_{Ml} & \frac{4\pi\alpha}{R_A} \left( \frac{R_N}{R_A} \right)^l \\
V_{El} & \frac{4\pi\alpha}{R_A} \left( \frac{R_N}{R_A} \right)^{l-1} \\
V_{Sch} & \frac{4\pi\alpha}{R_A} \left( \frac{R_N}{R_A} \right)^3 
\end{array}
\]

Can we find an interaction that gives a larger EDM than Schiff? We need a PVTV effect, and as little suppression as possible.

We can go to 2-$\gamma$ exchange

Combining $E_1$ and $E_2$ multipoles can give PVTV effect

They can also be recoupled to total $J=1$ ($E_1$-$M_1$ also possible)
Siegert’s theorem

Transverse electric multipoles can be written using a gradient

\[ E_{lm} = iR_N \sqrt{\frac{l+1}{l}} \int d^3y \vec{\nabla} \left[ \left( \frac{y}{R_N} \right)^l Y_{lm} \right] \cdot \vec{j}_N \]

Partial integration makes \( \vec{\nabla} \cdot \vec{j}_N \) appear,

which is equal to \( \frac{d\rho_N}{dt} \) by current conservation

Final result is

\[ E_{lm} = \sqrt{\frac{l+1}{l}} R_N [C_{lm}^N, H_N] \]

where \( H_N \) is the nuclear Hamiltonian.

This shows that these multipoles have no diagonal M.E.’s
Transverse electric multipoles have no static nuclear moments.

In order to compare the effects of E1-E2 combination with Schiff, we should compare using a nuclear energy denominator

\[ V_{E1-E2}^{\text{eff}} \sim V_{E1} \frac{1}{E_0 - E_n} V_{E2} \]
Naive comparison

So the E1-E2 effective interaction has size

$$V_{E1-E2}^{\text{eff}} \sim V_{E1} \frac{1}{E_0 - E_n} V_{E2} \sim \frac{4\pi \alpha}{R_A} \cdot \frac{1}{\Delta E_N} \cdot \frac{4\pi \alpha}{R_A} \frac{R_N}{R_A}$$

$$= (4\pi \alpha)^2 \frac{R_N}{\Delta E_N R_A^3}$$

Compare this with Schiff moment interaction

$$V_{\text{Sch}} \sim (4\pi \alpha) \frac{R_N^3}{R_A^4}$$

$$\frac{V_{E1-E2}^{\text{eff}}}{V_{\text{Sch}}} \sim \frac{4\pi \alpha}{\Delta E_N R_N} \left( \frac{R_A}{R_N} \right)$$

E1-E2 is enhanced compared to Schiff moment!
Problems with iterating Breit

1. Crossed diagram is ignored

If electrons are relativistic, this is not small

2. Derivation of Breit interaction takes the step

\[
\frac{i}{k^2} = \frac{i}{k_0^2 - \tilde{k}^2} \rightarrow -\frac{i}{\tilde{k}^2}
\]

Not correct for inelastic scattering, which we have
Time-ordered perturbation theory

“Old-fashioned” perturbation theory, solves BOTH problems

1. Start with a normal Feynman amplitude

2. TOPT rewrites it as sum over all time-orderings of vertices

3. Propagators $\frac{i}{k^2}$ turn into energy denominators

   Denominators show which time-orderings are important

   Also allows direct connection to non-relativistic calculation

(derivation in Sterman’s QFT textbook)
Time-ordered perturbation theory

Trivial example: scalar propagator

\[
\frac{i}{k^2 - m^2 + i\epsilon} = \frac{1}{2\omega_k^-} \left( \frac{i}{k^0 - \omega_k^- + i\epsilon} - \frac{i}{k^0 + \omega_k^- - i\epsilon} \right)
\]

\[
= \frac{1}{2\omega_k^-} \left[ \frac{i}{p_1^0 - (p_1^0 + \omega_k^-) + i\epsilon} + \frac{i}{p_2^0 - (p_2^0 + \omega_k^-) + i\epsilon} \right]
\]

where

\[
\omega_k^- = \sqrt{k^2 + m^2}
\]
Time-ordered perturbation theory

Trivial example: scalar propagator

\[
\frac{i}{k^2 - m^2 + i\epsilon} = \frac{1}{2\omega_k^{-1}} \left( \frac{i}{k^0 - \omega_k^{-1} + i\epsilon} - \frac{i}{k^0 + \omega_k^{-1} - i\epsilon} \right)
\]

\[
= \frac{1}{2\omega_k^{-1}} \left[ \frac{i}{p_1^0 - (p_1^0 + \omega_k^{-1}) + i\epsilon} + \frac{i}{p_2^0 - (p_2^0 + \omega_k^{-1}) + i\epsilon} \right]
\]

Those are energy denominators corresponding to the 2 possible time orderings of vertices
2-photon exchange in TOPT

There are $4!$ orderings each for box & crossed diagrams

Some orderings are highly suppressed

We want

1. massive particles traveling forward in time

2. only 1 intermediate state with nuclear excitations
Breit interaction comes from

Iterating Breit corresponds to assuming these 4 are leading

Only 1 of these is leading (1 nuclear excited state)

Adjust answer by factor of 1/4
2-photon exchange in TOPT

There are actually 6 leading diagrams - top middle is in Breit

Left and right diagrams sum to middle ones (accident?)

Crossed diagrams double the result - get back factor of $2 \times 2 = 4$
What did we learn?

This shows that the naive estimate earlier is essentially correct,
despite the incorrect use of the Breit interaction.

But we do want to make a better comparison to Schiff result

1. Use Siegert’s theorem and commutator trick for nuclear part

2. Relativistic enhancement near the origin
The E1-E2 interaction is

\[ V_{E1-E2} \approx \frac{(4\pi \alpha)^2}{15\sqrt{20\pi}} \frac{R_N}{R_A^3} \sum_i \beta_i \left( \frac{R_A}{x_i} \right)^3 Y_1(\hat{x}_i) \]

\[ \otimes \sum_n \frac{1}{E_0 - E_n} \left\{ \left[ \langle 0|E_1^N|n\rangle \otimes \langle n|E_2^N|0\rangle \right]_1 + [E_1^N \leftrightarrow E_2^N] \right\} \]

This is to be compared with the Schiff moment interaction

\[ V_{Sch} = \frac{4\pi \alpha}{R_A} \left( \frac{R_N}{R_A} \right)^3 \left[ R_A^4 \sum_i \left( \hat{\nabla}_i \delta^3(\tilde{x}_i) + \delta^3(\tilde{x}_i) \hat{\nabla}_i \right) \right] \otimes \left( \frac{\hat{S}}{R_N^3} \right) \]

Nuclear part and electronic part can be manipulated further.
Use Siegert’s theorem to rewrite transverse multipoles as commutator of charge multipoles and nuclear Hamiltonian

\[
\sum_n \frac{1}{E_n - E_0} \left[ \langle 0|E_{1m_1}^N|n\rangle \langle n|E_{2m_2}^N|0\rangle + (E_1^N \leftrightarrow E_2^N) \right]
\]

\[= - \sqrt{3}R_N^2 \sum_n (E_n - E_0) \left[ \langle 0|C_{1m_1}^N|n\rangle \langle n|C_{2m_2}^N|0\rangle + (C_1^N \leftrightarrow C_2^N) \right] \]

\[= - \sqrt{3}R_N^2 \langle 0| \left[ \left[ C_{1m_1}^N , H_N \right], C_{2m_2}^N \right] |0\rangle \]

Closure sum eliminates nuclear intermediate states
Commutator

C1 and C2 can be written using nucleon coordinates; assuming 2-body interactions are momentum-independent,

\[
\sum_{m_1, m_2} \langle 0 | \left[ \left[ C_{1m_1}^N, H_N \right], C_{2m_2}^N \right] |0\rangle \langle 10 | 1m_12m_2 \rangle
\]

\[
= -\frac{5\sqrt{6}}{4\pi} \frac{\hbar^2}{m_N R_N^2} \langle 0 | \frac{d_{N,z}}{R_N} |0\rangle
\]

This interaction couples to the nuclear EDM,

not the Schiff moment

Sushkov, Flambaum, Khriplovich 1984

Nuclear EDM not as well calculated as Schiff moment
Atomic enhancement

Electron wavefunctions near the origin are important

Solving Dirac equation with Coulomb potential of nucleus,

\[ u_{njl}(\vec{r}) = \begin{pmatrix} f_{njl}(r)\Omega_{jl}(\hat{r}) \\ g_{njl}(r)(-i\vec{\sigma} \cdot \hat{r})\Omega_{jl}(\hat{r}) \end{pmatrix} \]

with

\[ f, g \sim N \frac{Z^{1/2}}{R_A^{3/2}} \left( \frac{2Zr}{R_A} \right) \gamma^{-1} \]

\[ \gamma \equiv \sqrt{(j + 1/2)^2 - Z^2\alpha^2} \approx 0.8 \]

Note the \( Z^{1/2} \) enhancement in normalization, and

characteristic length becoming \( R_A/Z \)
Atomic enhancement

For Schiff moment,

\[ \langle s_{1/2} | \vec{\nabla} \delta^3 (\vec{x}) | p_{1/2} \rangle \]

\[ = \int d^3x \delta^3 (\vec{x}) (f_s^\dagger (x) f_p (x) + g_s^\dagger (x) g_p (x)) \langle \Omega_{1/2,0} | \hat{x} | \Omega_{1/2,1} \rangle \]

\[ \approx N \int d^3x \delta^3 (\vec{x}) x^{2\gamma - 2} \langle \Omega_{1/2,0} | \hat{x} | \Omega_{1/2,1} \rangle \]

This is a negative power - blows up at the origin

Integral must be cut off at \( x = R_N \). Result is \( \sim 10^5 \) enhancement

\[ \langle s_{1/2} | \vec{\nabla} \delta^3 (\vec{x}) | p_{1/2} \rangle \]

\[ \approx \frac{Z^2 R}{R_A (\nu_s \nu_p)^{3/2}} \langle \Omega_{1/2,0} | \hat{x} | \Omega_{1/2,1} \rangle \quad R \sim 10 \quad \text{for large } Z \]
Atomic enhancement

For E1-E2, 
\[ \langle s_{1/2} | \beta \frac{\hat{x}}{x^3} | p_{1/2} \rangle \]
\[ = \int \frac{d^3x}{x^3} (f_s^\dagger(x)f_p(x) - g_s^\dagger(x)g_p(x)) \langle \Omega_{1/2,0} | \hat{x} | \Omega_{1/2,1} \rangle \]
\[ \approx N \int dxx^{2\gamma-3} \langle \Omega_{1/2,0} | \hat{x} | \Omega_{1/2,1} \rangle = N x^{2\gamma-2} R_{\max} \]

Same negative power, same cutoff at \( x = R_N \).

This time, there's only 1 power of Z
\[ \langle s_{1/2} | \beta \frac{\hat{x}}{x^3} | p_{1/2} \rangle \]
\[ \approx \frac{Z R}{(\nu_s \nu_p)^{3/2}} \frac{(Z \alpha)^2}{2\gamma - 2} \langle \Omega_{1/2,0} | \hat{x} | \Omega_{1/2,1} \rangle \]
Final comparison (preliminary)

Before incorporating atomic enhancement, I had 2 overall factors

\[
\frac{4\pi \alpha}{10R_A} \left( \frac{R_N}{R_A} \right)^3 \quad \text{for Schiff moment,}
\]

\[
(4\pi \alpha)^2 \frac{\sqrt{3}}{15\sqrt{20\pi}} \frac{\Delta E_N R_N^3}{R_A^3} \quad \text{for E1-E2,}
\]

with E1-E2 being larger by ratio of \(~135\).

Atomic enhancement is larger for Schiff by \(~Z\).

E1-E2 appears to give comparable atomic EDM as Schiff moment
Conclusions

• $R_N/R_A$ counting is a way to estimate the sizes of EDM contributions

• 2-$\gamma$ exchange between electrons and the nucleus allows transverse electric multipoles to generate atomic EDM, with less $R_N/R_A$ suppression than the Schiff moment term

• E1-E2 combination results in a coupling to the nuclear EDM, rather than the nuclear Schiff moment

• Despite the smaller relativistic enhancement, the new contribution appears comparable to Schiff. Nuclear EDM calculations are needed
Backup slides
Approximate calculation (old)
Giant dipole approximation

\[ \sum_{n \neq 0} (E_n - E_0) \langle 0 | C_1 | n \rangle \langle n | C_2 | 0 \rangle \]

This expression resembles

\[ \sum_{n \neq 0} (E_n - E_0) |0| C_1 | n \rangle |^2 \]

which is known to be dominated by the giant dipole resonance.

We make the ansatz that our expression is also GDR dominated

\[ \sum_{n \neq 0} (E_n - E_0) \langle 0 | C_1 | n \rangle \langle n | C_2 | 0 \rangle \]

\[ \approx E_{GDR} \langle 0 | C_1 C_2 | 0 \rangle \]
With these approximations, our final expression is

\[
V_{E1-E2}^{\text{eff}} \approx - (4\pi \alpha)^2 \frac{\sqrt{3}}{15\sqrt{20\pi}} \frac{E_{\text{GDR}} R_N^3}{R_A^3} \sum_{i=1}^{Z} \left( \frac{R_A}{x_i} \right)^3 Y_1(\hat{x}_i) \odot \{C_1^N, C_2^N \}_1
\]

We have a **numerical factor**, an **electronic multipole**, and

a **nuclear multipole**, which is charge dipole and quadrupole
coupled to J=1.
Toy model calculation

We compare this nuclear moment with Schiff in a toy model

“Shell model”: nucleons of $^{15}$N (J=1/2) in HO potential

In order to get PVTV nuclear moments, we insert

$$V_{CPV} \equiv \frac{G}{\sqrt{2}} \frac{\eta}{2m} \vec{\sigma} \cdot \vec{\nabla} \rho_{\text{core}}(\vec{y})$$

as a perturbation to the HO potential, so that

$$\langle \tilde{0} | \hat{O} | \tilde{0} \rangle = \sum_{n \neq 0} \frac{\langle 0 | \hat{O} | n \rangle \langle n | V_{CPV} | 0 \rangle}{E_0 - E_n} + \text{c.c.}$$

is the final result.
Toy model calculation

Schiff moment has overall 1/10 in the definition

$$\tilde{S} = \frac{1}{10} \int d^3 y \left( \frac{y^2 \vec{y}}{R_N^3} - \frac{5}{3Z} \frac{y^2 d_N}{R_N^3} \right) \rho_N(\vec{y})$$

so compare with 10 times $S$.

| Operators          | $\langle 0 | \hat{O} | 0 \rangle$ (normalized) |
|--------------------|----------------------------------|
| $10 \cdot S$       | -10.557                          |
| $\{ C_1^N, C_2^N \}$ | 11.931                           |

Nuclear moments are the same order,

as expected from the $R_N/R_A$ argument.
Final comparison

Comparing

\[ V_{E1-E2}^{\text{eff}} \approx -\left(\frac{4\pi\alpha}{15\sqrt{20\pi}}\right)^2 \frac{\sqrt{3}}{E_{GDR} R_N^3} \frac{E_{GDR} R_N^3}{R_A^3} \]

\times \sum_{i=1}^{Z} \left(\frac{R_A}{x_i}\right)^3 Y_1(\hat{x}_i) \odot \{C_1^N, C_2^N\} \]

with

\[ V_{\text{Sch}} = \left(\frac{4\pi\alpha}{10 R_A} \left(\frac{R_N}{R_A}\right)^3\right) \left[ R_A^4 \sum_i \left( \vec{\nabla}_i \delta^3(\vec{x}_i) + \delta^3(\vec{x}_i) \vec{\nabla}_i \right) \right] \odot (10 \tilde{S}) \]

the ratio of the numerical factors is

\[ \frac{4\pi\alpha}{\sqrt{15\pi}} \frac{E_{GDR} R_A}{E_{GDR} R_A} \approx 135 \]

taking reasonable values of \( E_{GDR} = 20 \text{ MeV}, R_A = 10^{-10} \text{ m} \)
Multipoles
Full expansion of Breit interaction

\[ V_{Cl} = -\frac{4\pi\alpha}{(2l + 1)R_A} \left( \frac{R_N}{R_A} \right)^l C_l^A \cdot C_l^N \]

\[ V_{Ml} = \frac{4\pi\alpha}{(2l + 1)R_A} \left( \frac{R_N}{R_A} \right)^l M_l^A \cdot M_l^N \]

\[ V_{El} = \frac{4\pi\alpha}{(2l + 1)R_A} \left( \frac{R_N}{R_A} \right)^{l-1} E_l^A \cdot E_l^N \]

\[ V_{E'l} = \frac{4\pi\alpha}{(2l + 1)R_A} \left( \frac{R_N}{R_A} \right)^{l+1} E_l^A \cdot E_l'^N \]

There are 2 kinds of transverse electric terms,

but one is larger by \( R_N / R_A \) counting.
Multipoles

List of electronic multipole operators

\[ C_{lm}^A \equiv \int d^3x \left( \frac{R_A}{x} \right)^{l+1} \rho_e(\vec{x}) Y_{lm}(\hat{x}) \]

\[ M_{lm}^A \equiv \int d^3x \left( \frac{R_A}{x} \right)^{l+1} \vec{Y}_{lm}(\hat{x}) \cdot \vec{j}_e(\vec{x}) \]

\[ E_{lm}^A \equiv R_A^{l+2} \int d^3x \left[ \vec{\nabla} \times \left( \frac{1}{x^{l+1}} \vec{Y}_{lm}(\hat{x}) \right) \right] \cdot \vec{j}_e(\vec{x}) \]

\[ E'_{lm}^A \equiv R_A^l \int d^3x \left[ \vec{\nabla} \times \left( \frac{1}{2(2l-1)x^{l-1}} \vec{Y}_{lm}(\hat{x}) \right) \right] \cdot \vec{j}_e(\vec{x}) \]

E’ is the relevant transverse electric operator
Multipoles

List of nuclear multipole operators

\[ C_{lm}^N \equiv \int d^3 y \left( \frac{y}{R_N} \right)^l \rho_N(\vec{y}) Y_{lm}(\hat{y}) \]

\[ M_{lm}^N \equiv \int d^3 y \left( \frac{y}{R_N} \right)^l \vec{Y}_{lm}^l(\hat{y}) \cdot \vec{j}_N(\vec{y}) \]

\[ E_{lm}^N \equiv \frac{1}{R_{N}^{l-1}} \int d^3 y \left[ \vec{\nabla} \times \left( y^l \vec{Y}_{lm}^l(\hat{y}) \right) \right] \cdot \vec{j}_N(\vec{y}) \]

\[ E'_{lm}^N \equiv \frac{1}{R_{N}^{l+1}} \int d^3 y \left[ \vec{\nabla} \times \left( -\frac{y^{l+2}}{2(2l + 3)} \vec{Y}_{lm}^l(\hat{y}) \right) \right] \cdot \vec{j}_N(\vec{y}) \]

\( E \) is the relevant transverse electric operator
Time reversal
Time reversal

Multipoles are either parity even or odd

- even: total charge (monopole), magnetic dipole, etc.
- odd: EDM, magnetic quadrupole, etc.

Properties of operators under time reversal is more subtle, especially when we consider products of operators.
Time reversal

The starting point is the relation \( \langle T\psi | T\phi \rangle = \langle \phi | \psi \rangle \)

Notice that the bra and ket get reversed.

Consider EDM in T conservation limit:

\[
\langle jj | C_{10}^N jj \rangle = [TC_{10}^N jj] \dagger (T jj)
\]
\[
= [C_{10}^N i 2^j j, -j] \dagger (i 2^j j, -j)
\]
\[
= \langle j, -j | C_{10}^N | j, -j \rangle
\]

Wigner-Eckart relates these by a minus sign \( \Rightarrow \) no EDM

Another way to say this: \( C_1^N \) does not behave like spin under T
Time reversal

For J=1 operators, TV moments come from operators that behave in the same way under T and complex conjugation.

Time reversal

Multipoles are either parity even or odd

even: total charge (monopole), magnetic dipole, etc.

odd: EDM, magnetic quadrupole, etc.

Properties of operators under time reversal is more subtle,
especially when we consider products of operators.
Time-ordered perturbation theory
Time-ordered perturbation theory

Steps to the derivation:

1. Write the energy-conserving delta functions at each vertex as

\[ \delta(p^0_{\text{in}} - p^0_{\text{out}}) = \int_{-\infty}^{\infty} dt \ e^{i(p^0_{\text{in}} - p^0_{\text{out}})t} \]

If an internal line, \( k \), starts at vertex with time \( t_i \)

and ends at vertex with time \( t_j \), then there is a factor

\[ e^{i p^0_k (t_j - t_i)} \]
Time-ordered perturbation theory

2. This factor, $e^{ip_k^0(t_j-t_i)}$, lets us do the integration over $p_k^0$ by closing the contour at infinity.

Contour integral picks up a pole from the propagator of this line, and the pole corresponds to the on-shell energy of the particle.

Result:

$$\int \frac{d^4p}{(2\pi)^4} \rightarrow \int \frac{d^3p}{(2\pi)^3 2\omega_k}$$

Any function of $k^0$ in the numerator is evaluated with on-shell energy, since that gives the residue
Time-ordered perturbation theory

3. We still have time integrals that we introduced at the start.

The integrand is now $e^{i(E_{\text{in}} - E_{\text{out}})t}$ with on-shell energies.

But whether the particle is ‘in’ or ‘out’ depends on

the time ordering of the vertices.

Split up the integral into regions, which correspond to orderings.

Then we can perform the integrals fully.

Result: an energy denominator for each intermediate state
Time-ordered perturbation theory

Why is it sufficient to consider

Justification comes from TOPT
Time-ordered perturbation theory

These have a pure atomic excitation as the last intermediate state

Compare with…
Time-ordered perturbation theory

...for example

This diagram has massive particles always traveling forward, and only 1 nuclear excitation.

But atomic excited state always appears with a photon, which makes the denominator not so small
